

# Outline :- $MID \rightarrow$ does 2D systems Berry curvature

Topological aspects of quantum matter

February 2021

Goal - to become very familiar about the consequences of effect Berry curvature / phase in electronic bands. To do calculations of toy models and understanding + explaining experiments.

Approach - this subject is at the cutting edge of solid state physics and be taught in many ways. I will use an approach that goes beyond my area of research but will be centred around experiments.

Books:

1. Supriyo Datta "Electronic Transport in Mesoscopic Systems" -- quantum Hall and mesoscopic physics **Q. Hall**
2. Shun-Qing Shen "Topological Insulators – Dirac equation in condensed matters"
3. **David Vanderbilt "Berry Phases in Electronic structure theory"**
4. Andrei Bernevig and Taylor Hughes "Topological insulators and topological superconductors"
5. Dan Ralph notes: arXiv:2001.04797 <https://arxiv.org/abs/2001.04797>

Other books:

1. Steve Girvin and Kun Yang "Modern Condensed Matter Physics" **1st to A&M**
2. Harald Böhm and Hans Lüth "Solid-state Physics"

Grading

*we'll pay more attention  
to expt details.*

solve problems  
in Mathematica  
quite intensively.

our  
perspective  
will be expt

2. Shun-Qing Shen "Topological Insulators – Dirac equation in condensed matters"
3. David Vanderbilt "Berry Phases in Electronic structure theory"
4. Andrei Bernevig and Taylor Hughes "Topological insulators and topological superconductors"
5. Dan Ralph notes: arXiv:2001.04797 <https://arxiv.org/abs/2001.04797>

Other books:

1. Steve Girvin and Kun Yang "Modern Condensed Matter Physics"
2. Harald Böhm and Hans Lüth "Solid-state Physics"

Grading

1. Roughly 60 % of the grade from 6+ home works
2. Exam and term paper remaining 40%; depends on interest of the participants

Key policy regarding home works:

1. Collaboration for HW is fine / copying is NOT OK. You have to acknowledge the names of people you have collaborated with for each question if you collaborate.

Key topics:

1. Basic mesoscopic physics
2. Quantum Hall physics
  - Landauer Buttikier approach
  - Hofstadter butterfly physics
3. Basic idea about electronic bands in solids
4. Tightbinding method to calculate band structure

this is where learning  
shall happen

*around 12/13 lectures*

2. Exam and term paper remaining 40%, depends on

#### Key policy regarding home works:

1. Collaboration for HW is fine / copying is NOT OK. You have to acknowledge the people you have collaborated with for each question if you collaborate.

#### Key topics:

1. Basic mesoscopic physics
2. Quantum Hall physics
  - Landauer Buttiker approach
  - Hofstadter butterfly physics
3. Basic idea about electronic bands in solids
4. Tightbinding method to calculate band structure
  - a. 1D chain of atoms
  - b. Graphene band structure
  - c. Inversion symmetry broken honeycomb lattice
5. Idea of Berry curvature, Berry phase, topological invariants
  - a. Valley Hall effect
  - b. Spin Hall effect
6. Interesting topological models
  - a. Su-Schreiber-Heeger model
  - b. Haldane model
  - c. Kane and Mele model

→ applicable  
→ mother  
topics

foundational

↑  
may be 1 or 2  
will be added

7. Chern bands
8. Topological insulators
9. Weyl semimetals
10. Majorana in condensed Matter systems + Topological superconductivity

What are your expectations from the course?

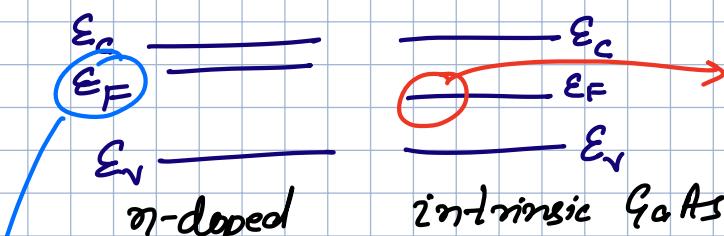

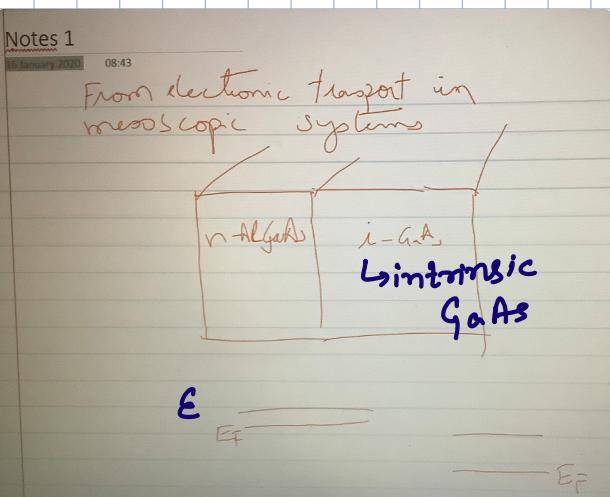

now we're  
talking

fractional quantum Hall

# Lecture 1

Main focus: Reduced dimensions & mesoscopic physics

From electronic transport in mesoscopic systems

Oftentimes we need 2D system

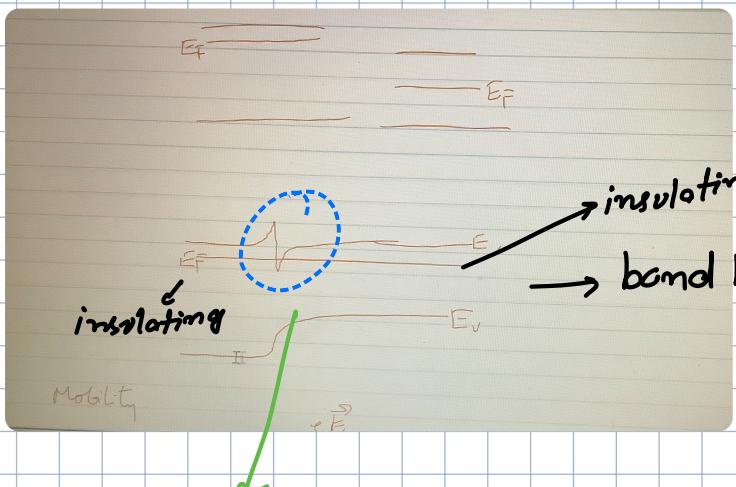

↙  
part of semiconductor technology

in layers → electrons move in layers like pages of a magazine

→ intrinsic

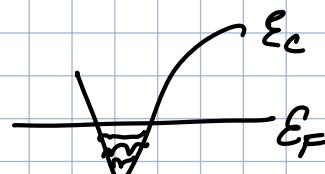

$n$ -doped

What happens if we bring an  $n$ -doped GaAs & i-GaAs together?

insulating  $\rightarrow$  self consistent sol'n of poisson eqn  
 $\rightarrow$  bond bending

Mobility

$\rightarrow$  Electrons are trapped in 3rd dimension  
(say 2-dimension)

now this is suppressed.

now the system behaves like a 2D system.

$\rightarrow$  "confinement in 1d"

}  $\Rightarrow$  now we can do Q. Hall physics here

world of 2D E's

similarly (loosely) situations are possible for

surface

- $\rightarrow$  gapless
- $\rightarrow$  free moving
- $\rightarrow$  topological

Bulk

- $\rightarrow$  gapped
- $\rightarrow$  block like

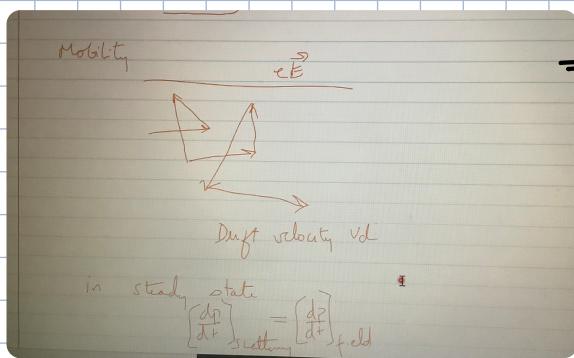

Topological insulators

Big point: new physics can be explored using ingenious engineering.

$\Rightarrow$  2DEG is key to realising topological materials

1DEG  $\rightarrow$  realisable, if confine<sup>in</sup> one more direction

# How does electron moves?  $\Rightarrow$  Drude model

$\Rightarrow$  bad assumption

all electrons respond to electric field  
X wrong

right  $\Rightarrow$  only near fermi-energy does interesting stuff happen.

Drift velocity  $v_d$

in steady state

$$\left[ \frac{dp}{dt} \right]_{\text{scattering}} = \left[ \frac{dp}{dt} \right]_{\text{field}}$$
$$m \frac{v_d}{z_m} = eE \Rightarrow v_{dI} = \frac{e z_m}{m} E$$
$$\mu = \left| \frac{v_d}{E} \right| = \frac{e z_m \text{ momentum}}{m}$$

scattering

momentum relax<sup>n</sup> time  
↳ elastic (doesn't change phase)

inelastic collisions

has some comp. that fluctuates in time.

Inelastic collision  $\Rightarrow$  scatterer has to be time dependent

big contributor

① "scattering due to phonons"

② "spin dof"

spin can have dynamics of its own & cause scattering

c.f. magnons

$\Rightarrow$  reduces timescales where electrons are coherent

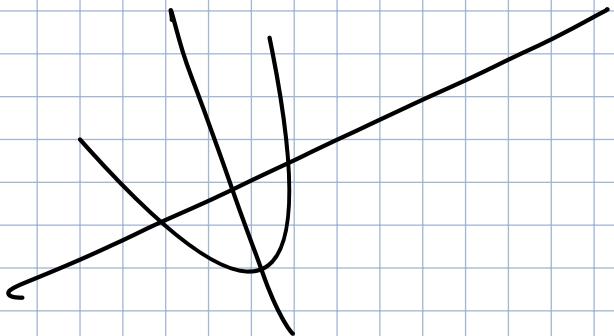

$\hookrightarrow$  if inelastic scatt. length is small  $\rightarrow$  coherence length  $\downarrow$

electrons  $\rightarrow$  electron waves  $\Rightarrow$  Gives quantized conductance

# Quantized conductance paper.

more channels/modes  $\rightarrow$  due to voltage

as we  $\uparrow$  the gate voltage in the circuit,  
more modes pop in.

$$f = e^{B(E-V) + 1}$$
